

## Assembly Types & Execution

In this chapter we will discuss about different assembly we have three different types of assemblies namely:

- ✓ **Private Assembly**
- ✓ **Shared Assembly**
- ✓ **Satellite Assembly**

Out of these, we are going to deep dive into first two & see them apart from normal basics. We are not going to see this chapter

We know .Net based projects are typically going to get format. In generic way we will call this output as an assembly. EXE/DLL - is not like any normal windows based binary packaging structure is different. It is suitable to support language interoperability, memory management, GC by C#.

Assembly (this is what we will refer to EXE/DLL) has different sections. Let us say, that we have created a project using language and have used some images like resources into the project. When we run (integer, character, custom classes etc.) in the project, we get an output i.e. assembly.

### What this assembly has?

Well, the output assembly has majorly four sections:

- ✓ **Assembly Metadata**
- ✓ **Resources**
- ✓ **Type Metadata**
- ✓ **MSIL**

Let us see these sections:

- ✓ **Assembly metadata:** This section contains information about the assembly like its name, version of the assembly, optionally company name, product name etc. which will be acting just like an index for rest of the assembly.
- ✓ **Resources:** This section will contain resources like images, icons, fonts etc.

compiler available with framework does the job of translating the code in to machine specific code.

JIT in turn has three different **flavors**:

✓ **Standard JIT Compiler:**

- Shipped by default
- Used / Called by default by CLR
- Compiles the code in to machine specific binary
- Keeps the code in RAM
- If application goes down/ machine's power cuts off, the code is gone!
- Next time – it starts again
- Suitable for web applications where the application keeps on running 24 X 7

✓ **Pre – JIT Compiler:**

- Need to call specifically
- Use **NGEN.EXE (Native Code Generator)** to generate machine specific binary format while installing the application on the machine.
- Converted code is stored on the secondary storage and loaded from there itself next time.
- Suitable for Windows applications / library kind of applications.

✓ **Ekono JIT Compiler**

- Just like standard JIT compiler, it stores the generated code in RAM, but wipes out from the RAM once the application exits. This means, during the same run, same code might be cleaned from the RAM number of times.
- It works as -> Compile MSIL on reference -> Store the code in RAM -> Wipe after execution -> Compile MSIL on reference again.
- Suitable for mobile based application, where memory need to be used effectively.

Let us discuss now, **how an assembly executes**:

Normal binary EXE (just like one you create using C++) has sections like text section, data section, binary statements etc. This structure is called assembly.

- ✓ Windows runtime realizes that it can execute the structure very well.
- ✓ It then, allocates memory for execution.
- ✓ Reads text section, data section & executes starting from entry point.

**Now, see what will happen around when you double click on the file.**

Wait! Before that let us discuss one more term – **EXE & DLLs:**

One of the important point to note here is by default **DLLs can't have their own memory for execution.**

They can't have their own memory for execution. **They are para**

It is just like a Client – Server terminology. **How come?**

See,

What Client does? – Always requests for something to Server.

What Server does? – Always responds to the client's requests.

Same here, if you see DLLs are meant for reference. They just execute. EXEs can refer the DLLS. What happens when the DLL is loaded?

**See here:**

- ✓ EXE is running & has its own memory under which DLLs run.
- ✓ EXE gives a call to DLL.
- ✓ As, we know now, DLLs can't have their own memory, they run in the same memory space.
- ✓ DLL loads itself into the EXE memory area (just like a Client).
- ✓ See from the Client – Server terminology: EXE requests some input & DLL replies with output.
- ✓ So, DLL is active as a Server & EXE is acting as a Client.
- ✓ But something more interesting is: Server (DLL) runs in the Client (EXE) process.
- ✓ So, DLLs are also called as In-Process Server (the Client). In short we refer these as In-Proc Server.

**Now, let us see what will happen around when you double click on the file.**

- ✓ What this DLL is? Let us discuss about this first & execution part.

## What is MSCORLIB? (Alias MSCOREE – Microsoft Common Environment)

**It is CLR (Common Language Runtime) – heart & soul of .NET**

### About Common Language Runtime:

CLR is a heart of .NET framework. It does lot of important task

- ✓ MSIL into native code conversion through JIT compiler
- ✓ Execution
- ✓ Memory allocation
- ✓ Garbage Collection
- ✓ Exception Handling
- ✓ Type Loader
- ✓ Security Check
- ✓ COM Marshalling
- ✓ Many more ....

Since, these are very core tasks, so is the CLR in terms of .NET.

If you have noticed above, it's a DLL. So what? - Obviously, it's a DLL for execution. Where will CLR get the memory? We know from ActiveX concept that ActiveX components don't have their own memory space & always execute inside the host application. What happens in this case? Will there be multiple CLRs when you run multiple .NET applications (EXEs) on your machine?

**CLR is a special kind of DLL. It can have its own memory for execution.**

If you remember, in VB 6.0, apart from conventional DLLs, we have ActiveX concept which can have its own memory for execution. It's a shared assembly library which needs to be referred & can have its own memory space.

But, we don't have such ActiveX concept here.

Rather **in terms of out of process memory, similar concept has been introduced in .NET**

We will see shared assembly concept in more detail later in this chapter.

- ✓ After this, the CLR takes over the control of environment & starts executing an assembly.
- ✓ So, what it does then?
- ✓ CLR starts reading the assembly top to bottom.
- ✓ First it reads the **assembly metadata** – with which it can determine the rest of the structure of an assembly.
- ✓ It then, **loads the resources, types** required to run the program.
- ✓ Then, It gives a call to **JIT compiler to convert native code**.
- ✓ Depending on what type of application (Web/WPF/Console/Windows Service), the **JIT compiler (Standard/Pre/Ekono)** can be called upon the case.

### **Who allocates the memory for application EXE or in this case of DLL?**

Obviously, CLR does this. When?

When it comes in picture for the first time, it gets some 'X' amount of memory for management. Then onwards CLR will act as if a virtual computer. Any program (assembly running) under the CLR will ask to CLR for an allocation.

**Any program will not directly talk with OS at any time. So, CLR acts as a bridge between application and OS.**

So, EXE gets the memory from CLR. We will discuss about the memory management, garbage collection algorithm in details later in the book.

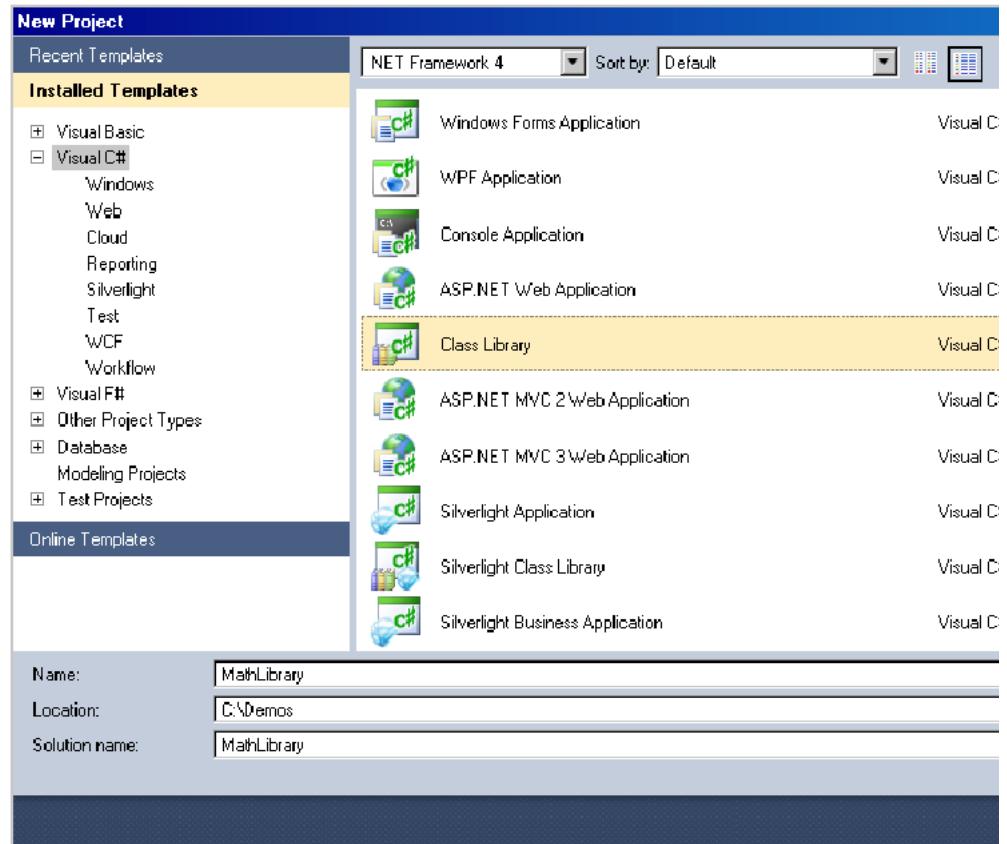

We talked about the EXE, DLL assemblies. But what are private & shared assemblies?

By default every assembly is a private assembly.

Let us create a program to understand private assembly concept.

#### **Steps:**

1. Start Visual Studio 2010 by clicking on: **Start -> All Programs -> Microsoft Visual Studio 2010 -> Microsoft Visual Studio 2010 Icon**
2. Click on: **File -> New -> Project**

4. Click on Ok Button.

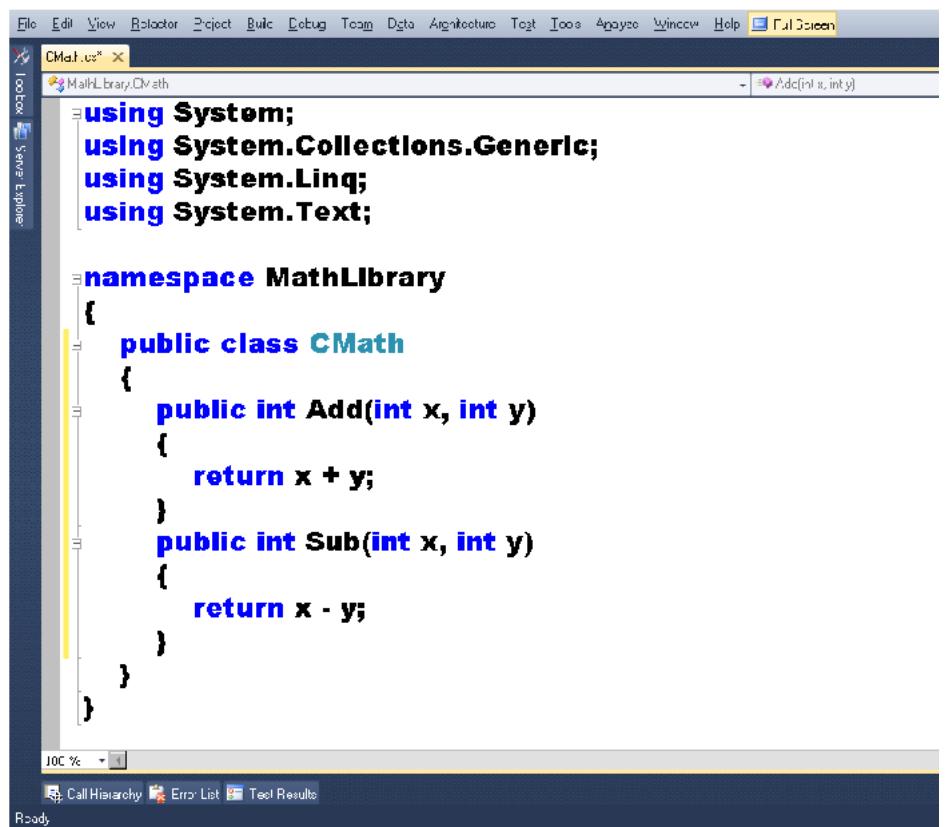

5. Name the class file as CMath.cs in the solution explorer as we have done in step 4. Now open the class file CMath.cs and write the code as shown:

```

using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

namespace MathLibrary
{
    public class CMath
    {
    }
}

```

```

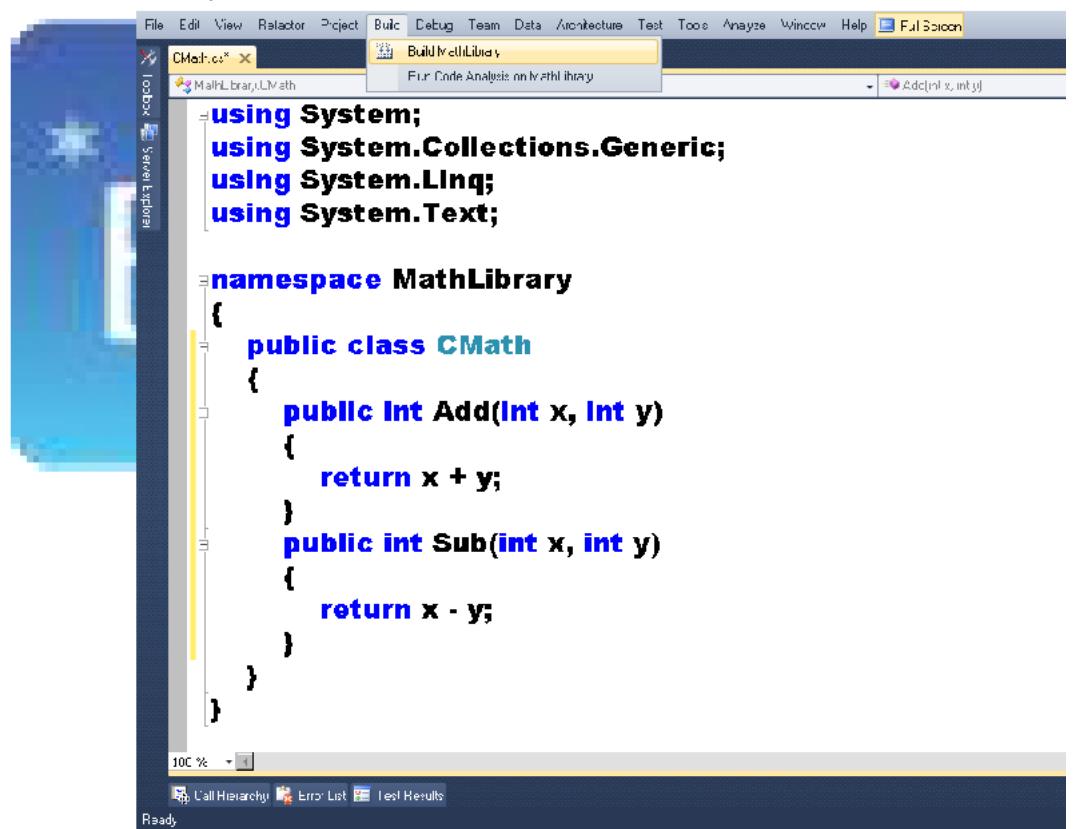

using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

namespace MathLibrary
{
    public class CMath
    {
        public int Add(int x, int y)
        {
            return x + y;
        }

        public int Sub(int x, int y)
        {
            return x - y;
        }
    }
}

```

## 7. Compile the code:

```

using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

namespace MathLibrary
{
    public class CMath
    {
        public int Add(int x, int y)
        {
            return x + y;
        }

        public int Sub(int x, int y)
        {
            return x - y;
        }
    }
}

```

Right click on the solution explorer & click on Open Folder

The screenshot shows the Microsoft Visual Studio interface with the title bar "Math library - Microsoft Visual Studio". The menu bar includes File, Edit, View, Refactor, Project, Build, Debug, Team, Data, Architecture, Test, Tools, Analyze, Window, Help. The toolbar has various icons for file operations like Open, Save, and Build. The Solution Explorer on the left shows a project named "MathLibrary" with a file "CMATH.cs" selected. The code editor window displays the following C# code:

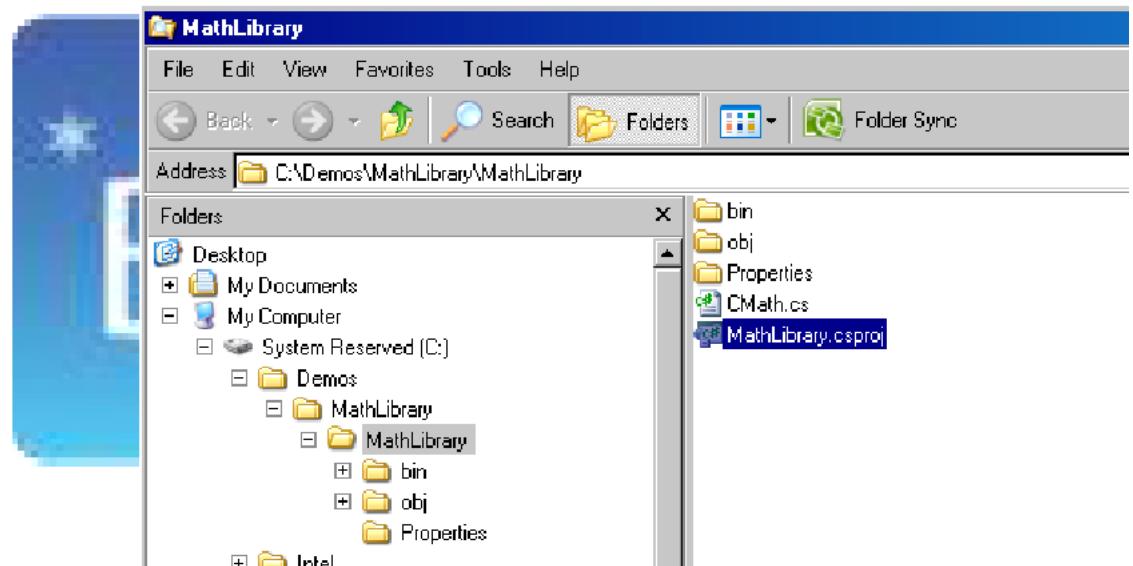

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

namespace MathLibrary
{
    public class CMath
    {
        public int Add(int x, int y)
        {
            return x + y;
        }

        public int Sub(int x, int y)
        {
            return x - y;
        }
    }
}
```

The status bar at the bottom indicates "Ready".

## 9. It opens:

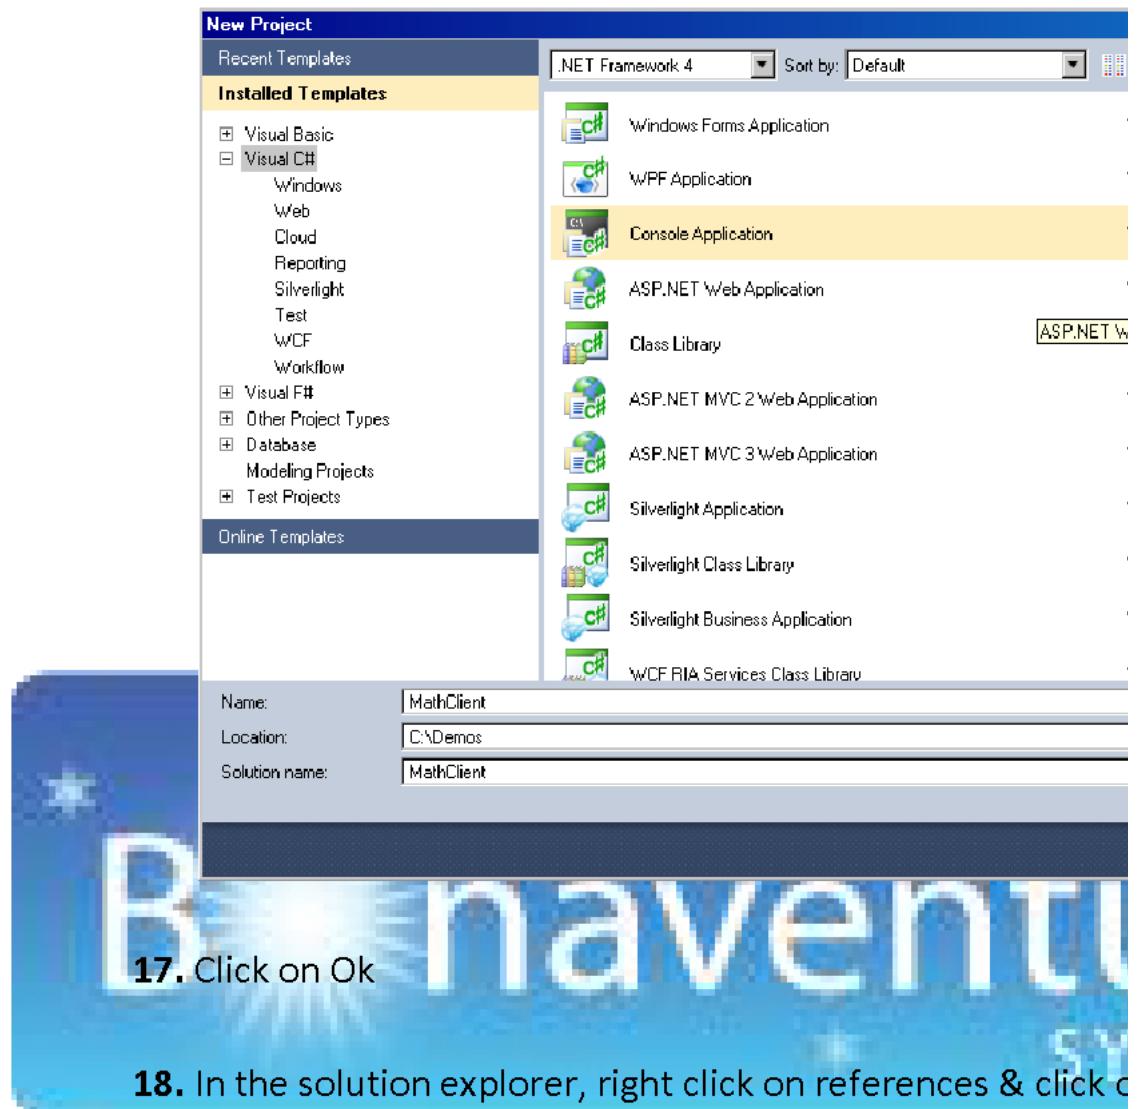

## 10. Go to bin-> debug folder

- 11.** You will an output assembly (DLL) created called MathLibrary.dll. Click on the DLL, it will not execute.
- 12.** This is server (DLL) program, Now let us create a client (EXE).
- 13.** See on Next Page:

- 14.** Start one more time Visual Studio 2010 by clicking on: **Start > Microsoft Visual Studio 2010 ->Microsoft Visual Studio 2010**
- 15.** Click on: **File -> New -> Project**
- 16.** In the dialog: Choose C# as a language → Choose project type Application → Name the project as MathClient as shown:

- 17.** Click on Ok

- 18.** In the solution explorer, right click on references & click on

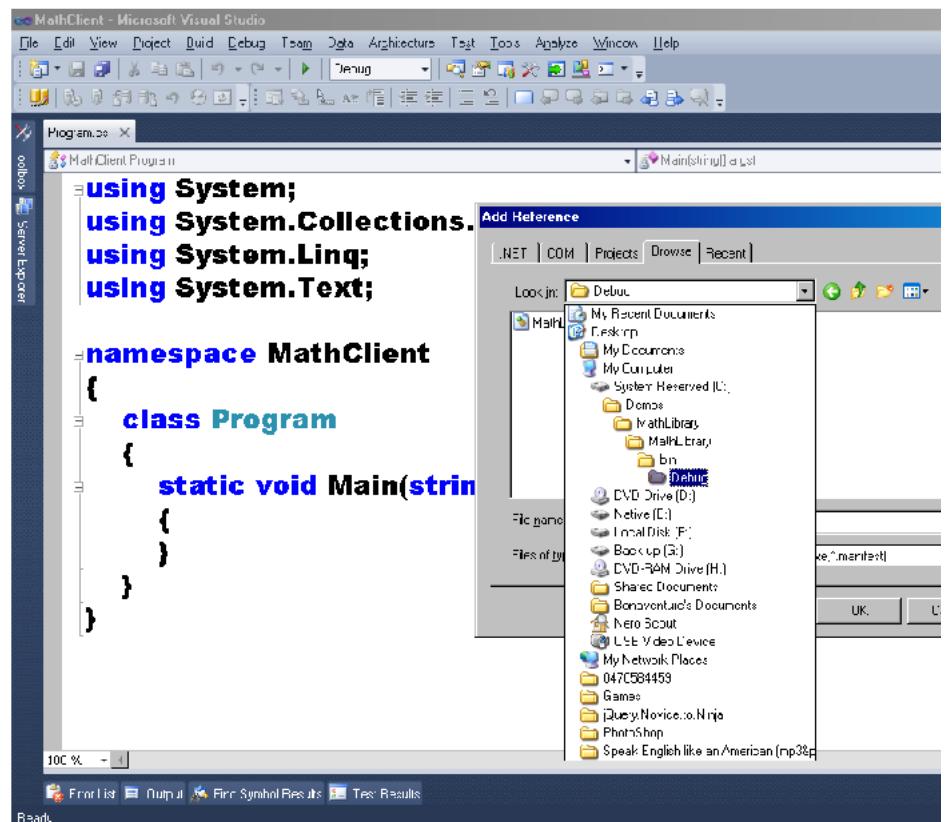

```

using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

namespace MathClient
{
    class Program
    {
    }
}

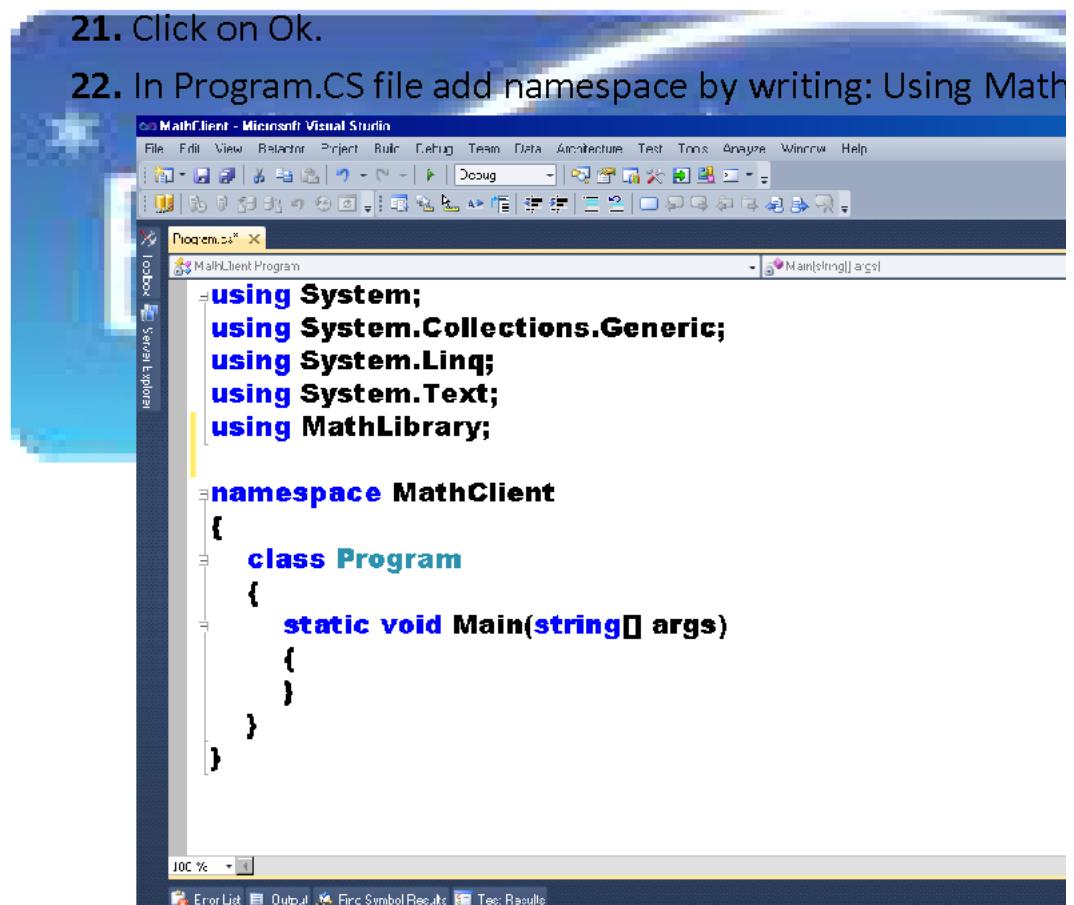

```

**20.** Navigate to previously created DLL.

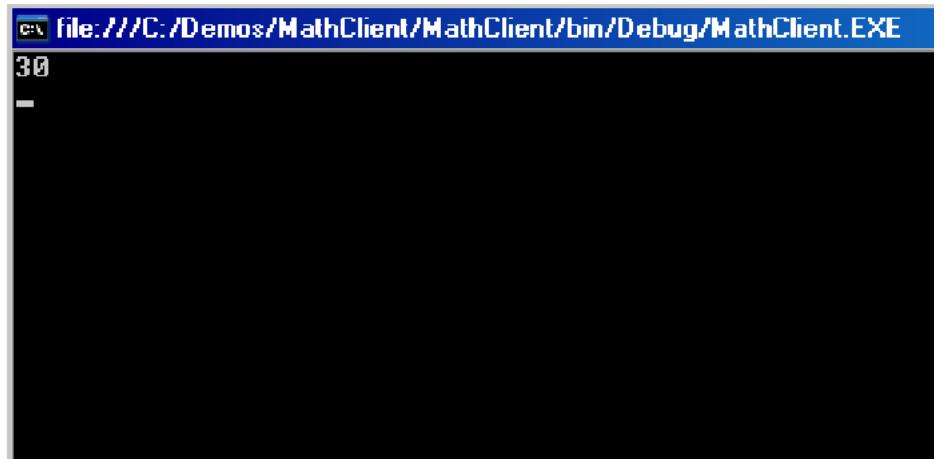

**21.** Click on Ok.

**22.** In Program.CS file add namespace by writing: Using Math

24. Press F5 to run the program. You should see the output as

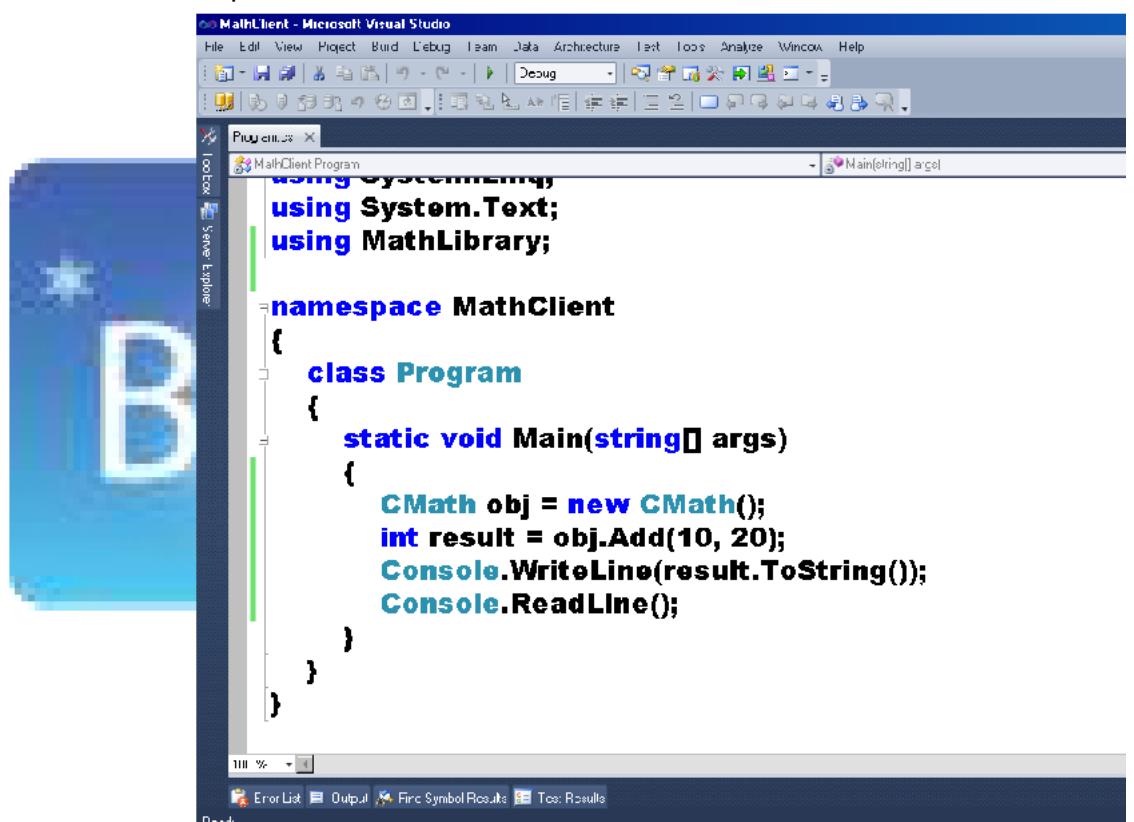

```
file:///C:/Demos/MathClient/MathClient/bin/Debug/MathClient.EXE
30
-
```

25. So, the code is fine. Client is calling Server & we are getting the output.

26. All the assembly execution that we discussed above is completed.

27. Now, right click on solution explorer. Click on Open Solution Explorer.

```
using System;
using System.Text;
using MathLibrary;

namespace MathClient
{
    class Program
    {
        static void Main(string[] args)
        {
            CMath obj = new CMath();
            int result = obj.Add(10, 20);
            Console.WriteLine(result.ToString());
            Console.ReadLine();
        }
    }
}
```

28. Observe now, what the folder bin-> debug has:

- 29.** If you see, there is a copy of MathLibrary.DLL created in the Client's memory.
- 30.** It's literally copy – paste. Now what will happen if we replace the MathLibrary.DLL? Will the change reflect in client program?
- 31.** Answer is **No**.
- 32.** It will not unless & until the Client EXE program is compiled again.
- 33.** This current copy of the DLL is called as **Private copy** or **Private DLL**.
- 34.** If we build another Client program then that client will also have the same DLL.
- 35.** If we run both the clients at the same time on same machine, both will be referring to its own copy.
- 36.** If one of the client's private DLL gets corrupt then that will not affect other client running.
- 37.** Which means with private copy helps in running independently but at the same time, it also generates a problem.
- 38.** These DLLs run inside the memory of client EXEs.
- 39.** The problem is when all clients' needs to be referring new DLL then everyone should be either recompiled or old copy should be replaced with the new one!
- 40.** Can't there be any location where in if we replace the DLL, all the machine will get it from the same location.
- 41.** This is where shared assembly concept comes in picture.

All the shared assemblies are registered with .NET registry (.NET GAC) & registered with Windows registry & can be seen at [Native Drive]:\\Windows\\Assembly folder.

Address	E:\\WINDOWS\\Assembly	Assembly Name	Version
Folders			
My Computer		Accessibility	2.0.0.0
System Reserved (C:)		ADODBC	7.0.330.0
DVD Drive (D:)		AspNetMIMEExt	2.0.0.0
Native (E:)		CppCodeProvider	8.0.0.0
ConvertTemp		CRVsPackageLib	10.5.37.0
Documents and Settings		CrystalDecisions.CrystalReports.Design	10.5.37.0
Inetpub		CrystalDecisions.CrystalReports.Engine	10.5.37.0
Intel		CrystalDecisions.Data.AdoDotNetInterop	10.5.37.0
MOSS2010 VPC		CrystalDecisions.Enterprise.Desktop.Report	10.5.37.0
MSOCache		CrystalDecisions.Enterprise.Framework	10.5.37.0
Program Files		CrystalDecisions.Enterprise.InfoStore	10.5.37.0
SharePoint2010 Developer		CrystalDecisions.Enterprise.PluginManager	10.5.37.0
SilverlightApplication1		CrystalDecisions.Enterprise.Viewing.ReportSource	10.5.37.0

- ✓ This DLL is private assembly. This is just a simple coded DLL done apart from compilation.
- ✓ When CLR gives a call while executing this DLL then it simply uses the EXE's memory space without even checking whether it can execute. Somebody might have written /tampered the DLL while compilation.
- ✓ To enable this security checking, the above mentioned key pair is used.
- ✓ These are special prime numbers (one prime other co-prime) generated with the help of an algorithm called RSA (stands for three people – R - Rivest, S - Shamir, A - Adleman).
- ✓ One number is called private key & other is public key.
- ✓ Later on after generating these keys, hashing algorithm is applied on assembly. The contents of assembly are hashed (encrypted) using RSA algorithm with private key as a second operand. This hash code is stored in assembly metadata.
- ✓ The encrypted output can't be decrypted. Then what's the use of this?
- ✓ This hash code acts just like a checksum bits. Later on, when assembly is loaded by CLR, it simply does the same task of hashing again and checks old hash (from metadata) with new hash. If the comparison fails then there is no problem. But if the comparison fails then the assembly is tampered.
- ✓ Public key is used for unique identification of the assembly.

Since the shared assembly has to be loaded in shared memory area outside the client EXE, CLR must be careful while loading any assembly. It checks the same using above discussed process. In the discussed process, the assembly must have private – public key pair assigned to it.

So, to create a shared assembly one should have key pair assigned to it.

Let us create one pair & attach with MathLibrary.DLL.

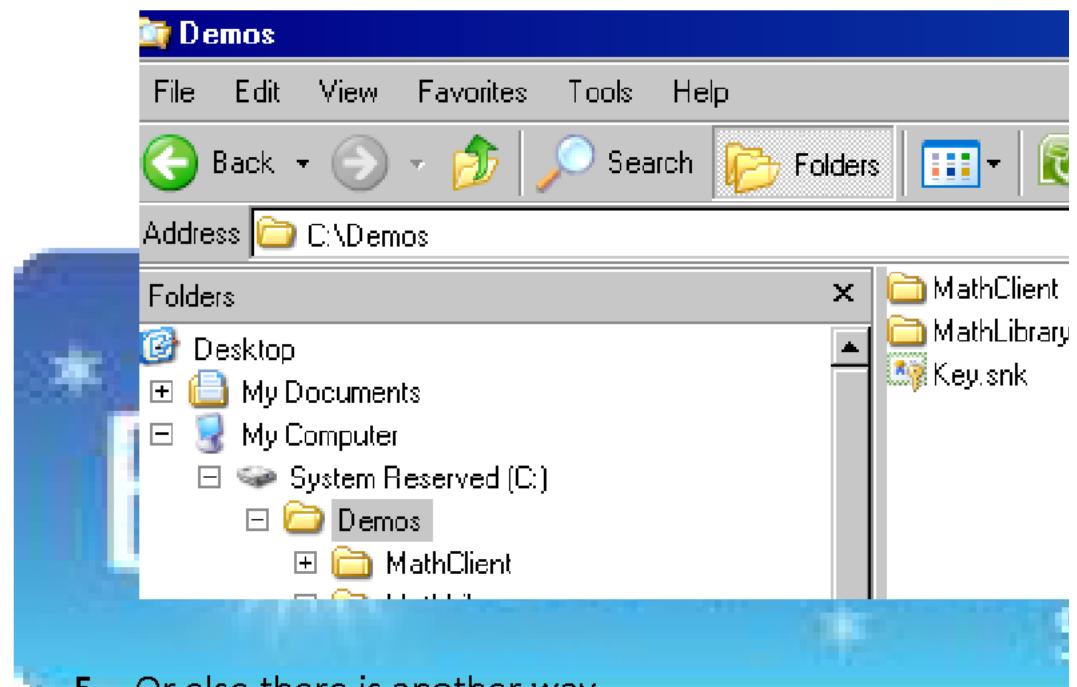

1. Create a strong name key pair (private key + public key) using the following command:

```
Visual Studio Command Prompt (2010)
C:\Demos>sn -k Key.snk
Microsoft (R) .NET Framework Strong Name Utility  Version 4.0.30319.1
Copyright (c) Microsoft Corporation. All rights reserved.

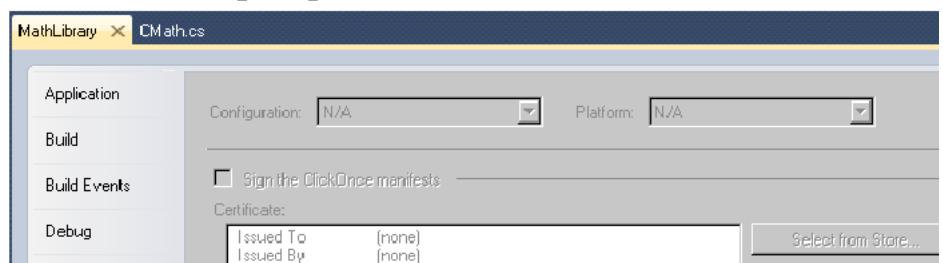

Key pair written to Key.snk

C:\Demos>
```

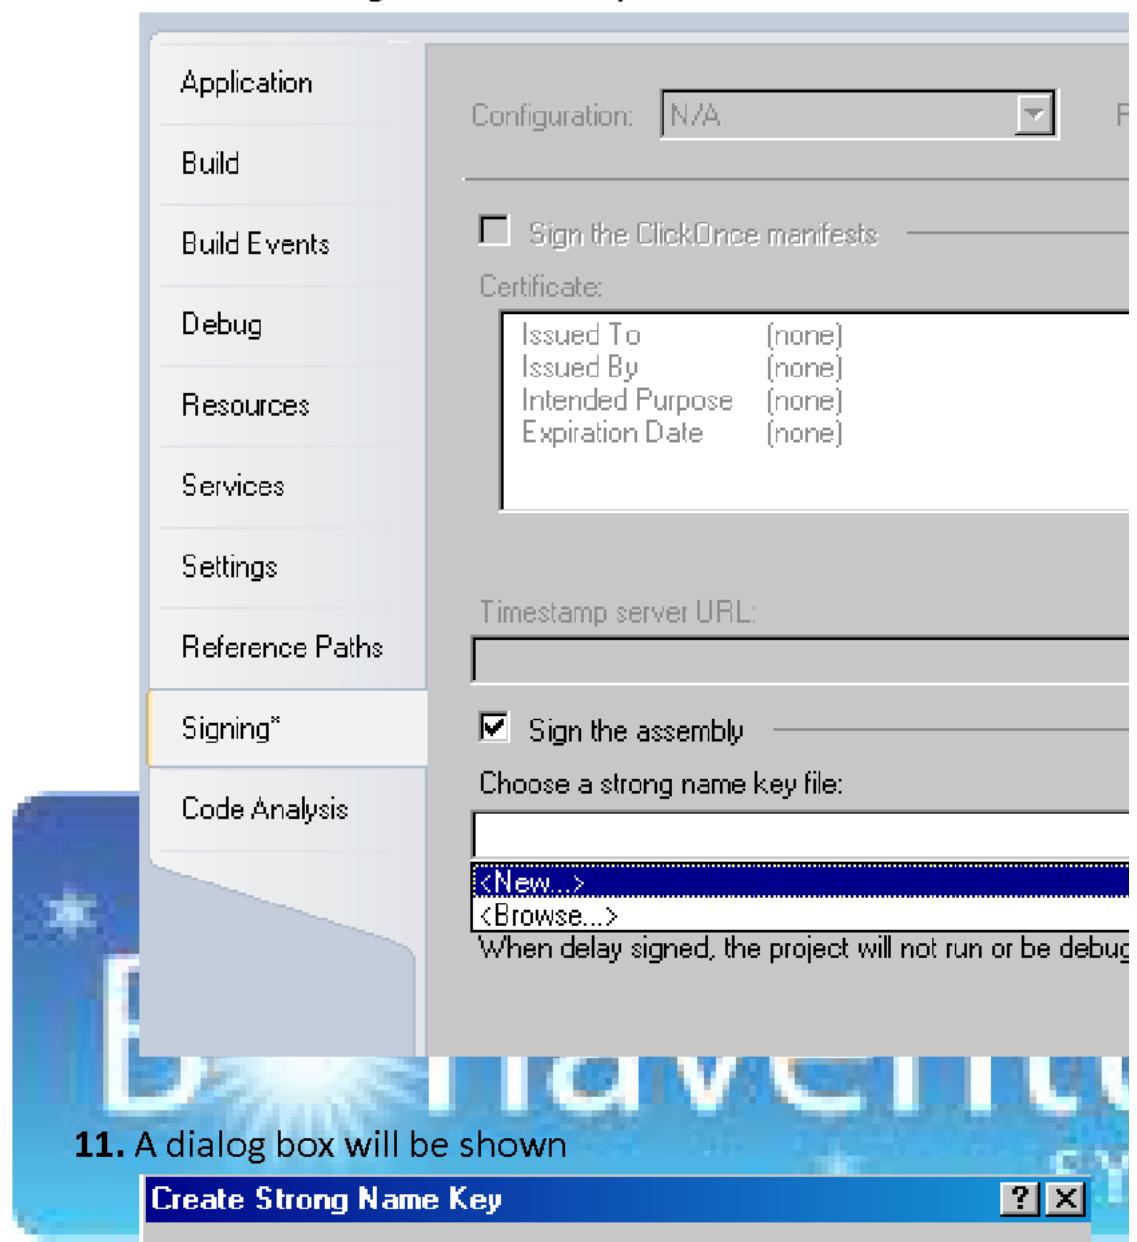

4. On C drive, see the file created.

5. Or else there is another way.
6. Right click on the MathLibrary project under solution exp
7. Click on Properties menu item.
8. Click on the Signing Tab

9. If you choose browse then you can navigate to the file that v Key.snk & compile the project.
10. Else click on sign the assembly then choose <New> from the

11. A dialog box will be shown

- 14.** After this click on Ok & compile the project.
- 15.** You will see that the file exists in the solution explorer.
- 16.** Now, we have key pair added to the DLL or assembly.
- 17.** To install this assembly, into the global assembly cache (GAC area, Click on start → All Programs → Microsoft Visual Studio Tools → Visual Studio Command Prompt
- 18.** Give a command “gacutil /i <assembly path>”. Hit enter.

```
C:\>
C:\>gacutil /i C:\Demos\MathLibrary\MathLibrary\bin\MathLibrary.dll
Microsoft (R) .NET Global Assembly Cache Utility.  Version 4.0.30319.1
Copyright (c) Microsoft Corporation. All rights reserved.

Assembly successfully added to the cache

C:\>_
```

- 19.** Now open the <Native Drive>:\\Windows\\Assembly Folder.
- 20.** You should see the MathLibrary.dll installed.
- 21.** Now, recompile the MathClient EXE client program.

22. See, if it runs. It works.
23. In the output folder you will not see private copy of the Matl shared now just like CLR DLL!
24. We have successfully created shared DLL.

Generally, while executing EXE program whenever CLR sees any DLL **DLL is first searched in GAC area** by CLR. If not found in the GAC a local copy. If not found there as well then it throws an exception.

### **What will happen if there are two copies one at the shared area private copy with EXE & their versions are different?**

Generally, a DLL is referred with which reference, the EXE is built. So if with 1.0 version then CLR will always look for 1.0 versioned DLL. If it is referred as a shared assembly else private copy is searched.

But to make sure that specific version is always referred one must refer to the shared assembly.

### **What will happen if there are two versions of the same DLL inside the assembly & which DLL will the CLR refer?**

Same answer. It will refer the DLL with which reference, the EXE is built.

### **What if one wants to redirect reference to other versioned DLL in the EXE program?**

If you want to target some other version of the DLL for the EXE but still use the same DLL then you will have to tell CLR to refer other version of the same DLL.

## Probing Element in Application (EXE) Configuration file:

```
<configuration>
  <runtime>
    <assemblyBinding xmlns="urn:schemas-microsoft-com:asm.v1">
      <dependentAssembly>
        <assemblyIdentity name=""
          publicKeyToken="
```

This is where we will end our chapter.

Do see following list of issues that you may face while doing practicals

### Known Issues while practicing:

- 1. I can't create strong name key pair using command prompt have permission. What do I do?**

Do see that you are working as a local administrator while Studio Command Prompt or else try to use visual studio with click on the project under solution explorer & then choosing from vertical tabs.

- 2. How do I uninstall the assembly from GAC?**

Use command **GACUTIL /u "<Assembly to be uninstalled>"** in Command Prompt.

- 3. Can I install the assembly using drag & drop?**

Yes, but you need to make sure that assembly is complete such as – assembly should have strong name key pair, etc.

- 4. Can I copy & paste?**

No, you won't be able to copy & paste the assembly but you can copy & paste the assembly.

- 5. How do I install the assembly on client machine? Since I have created the Setup by my own. Is it possible to install the DLL assembly on client machine without installing the EXE project set up on the client end?**

Yes, Right click on the EXE project under solution explorer -> under prebuilt command option you need to write the command **GACUTIL /i "<Assembly to be uninstalled>"** which will be executed while client installs the EXE project on the machine. You need to make sure that the assembly DLL is also packaged in the setup project which you will hand over to the client.

Do write an email in case of other queries to:
